Replit Usage Evidence

Future Fit (Aligna)

SDC Hackathon - Sponsor Resource and Prototype Development Record

Sponsor resource	Replit Core access and Replit Agent usage provided through the official SDC sponsorship programme.
Evidence scope	Initial prototype, AI-assisted interface exploration, Agent activity and account-level AI usage.
Final implementation	Refined in the team's local Node.js repository and deployed through Vercel.

Prepared from the team's Replit project screenshots and account usage evidence. Redemption codes, passwords and private account credentials are intentionally excluded.

1. Purpose and Sponsor-Provided Resource

This document provides evidence that the team used the official SDC-sponsored Replit resource during the development of Future Fit (Aligna). Replit was used for the initial prototype and AI-assisted interface exploration. The final implementation was later refined locally and deployed through Vercel.

Sponsor	Replit
Resource	Replit Core access and Replit Agent AI usage provided through the official SDC sponsorship programme.
Primary use	Rapid prototyping, requirements exploration, interface iteration and early seeker-workspace design.
Final runtime	Local Node.js development, Firebase services and Vercel deployment.

The sponsor resource was valuable for rapid prototyping and AI-assisted interface exploration, but it was not essential to the core runtime of the final product. The final implementation can run in the team's local Node.js environment and was deployed through Vercel.

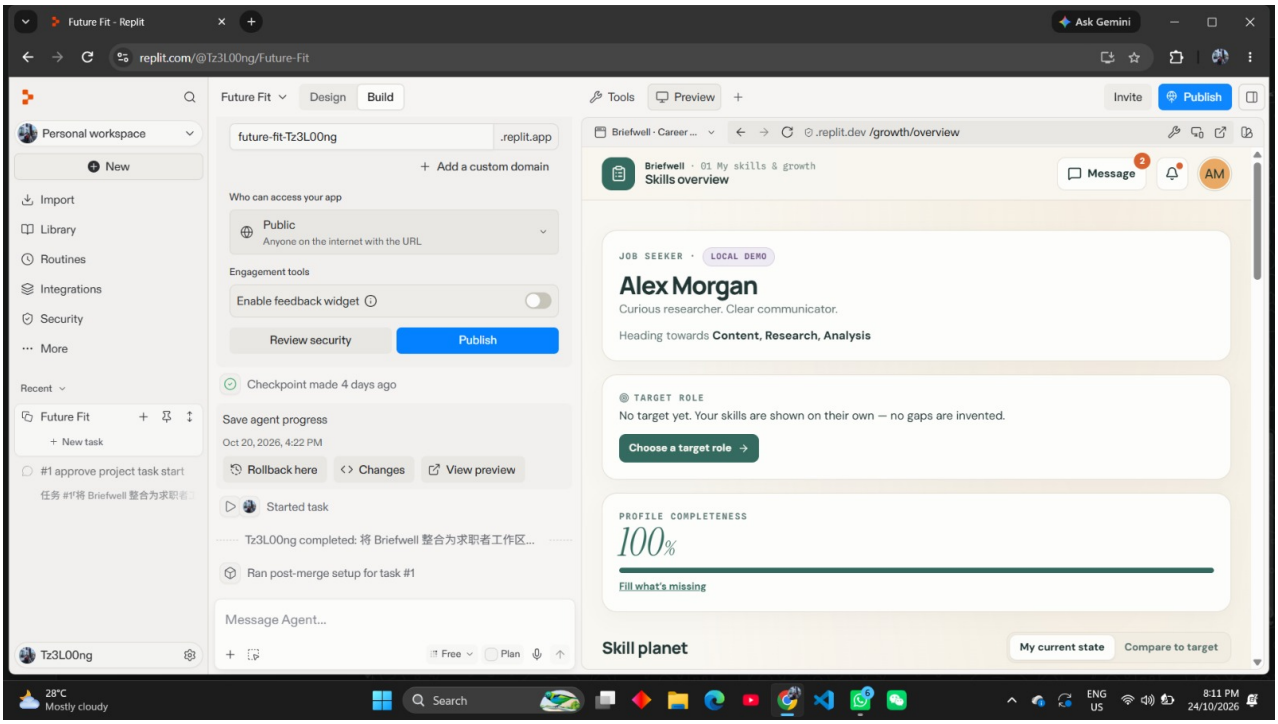

Figure 1. Replit Core workspace, Future Fit project title and prototype publishing configuration.

The publishing panel and development preview are shown as evidence of the Replit project environment. This screenshot is not presented as proof of a successful final production deployment on Replit.

2. Replit Agent Development Process

The team provided Replit Agent with a detailed brief describing the existing product, the seeker workspace, skills analysis, company exploration, matching, learning routes and messaging requirements. The brief also asked the Agent to reuse the existing product structure, data logic, navigation and permissions where possible.

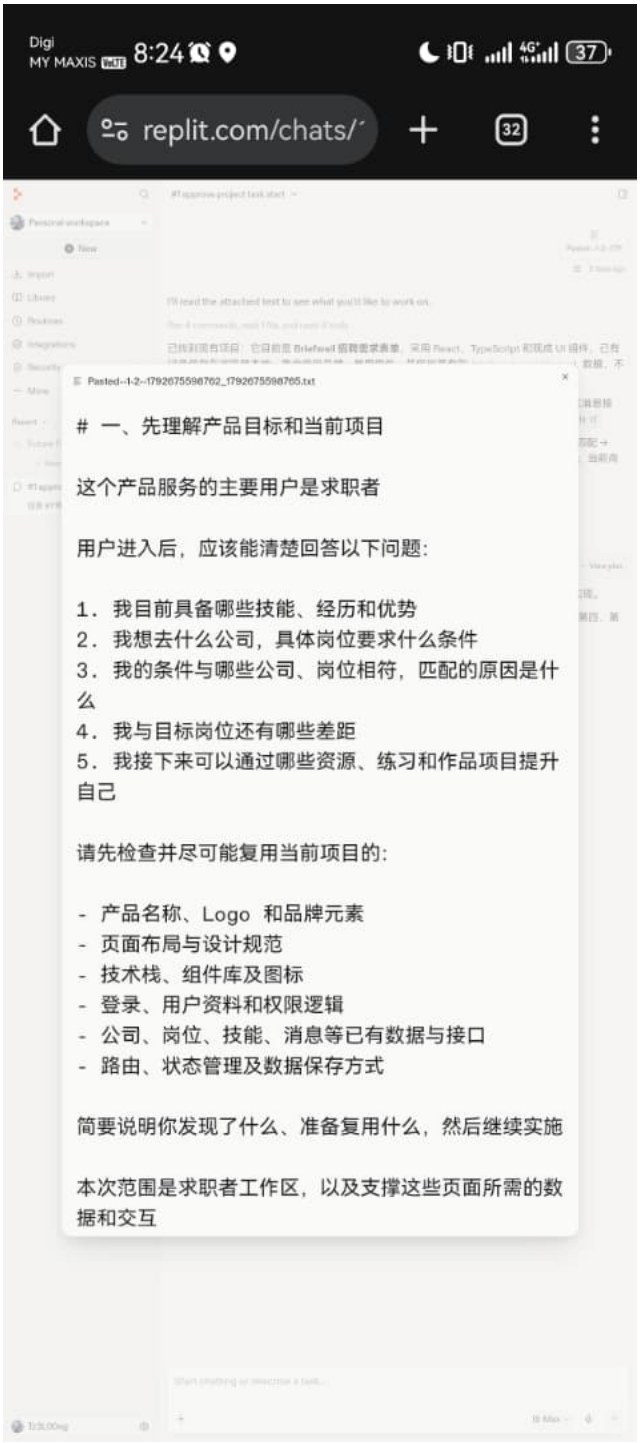

Figure 2. Initial product requirements and implementation brief provided to Replit Agent.

After receiving the brief, Replit Agent processed the request and created a task for integrating the early job-seeker workspace. The task record shows the Agent working on the product requirements rather than only answering a general question.

Figure 3. Replit Agent task processing and completion record.

3. Prototype Preview and Iteration

The Replit project was used to preview and iterate on the early Future Fit experience. The visible prototype includes a job-seeker profile, target-role section, profile completeness indicator, skills overview and skill-planet interface.

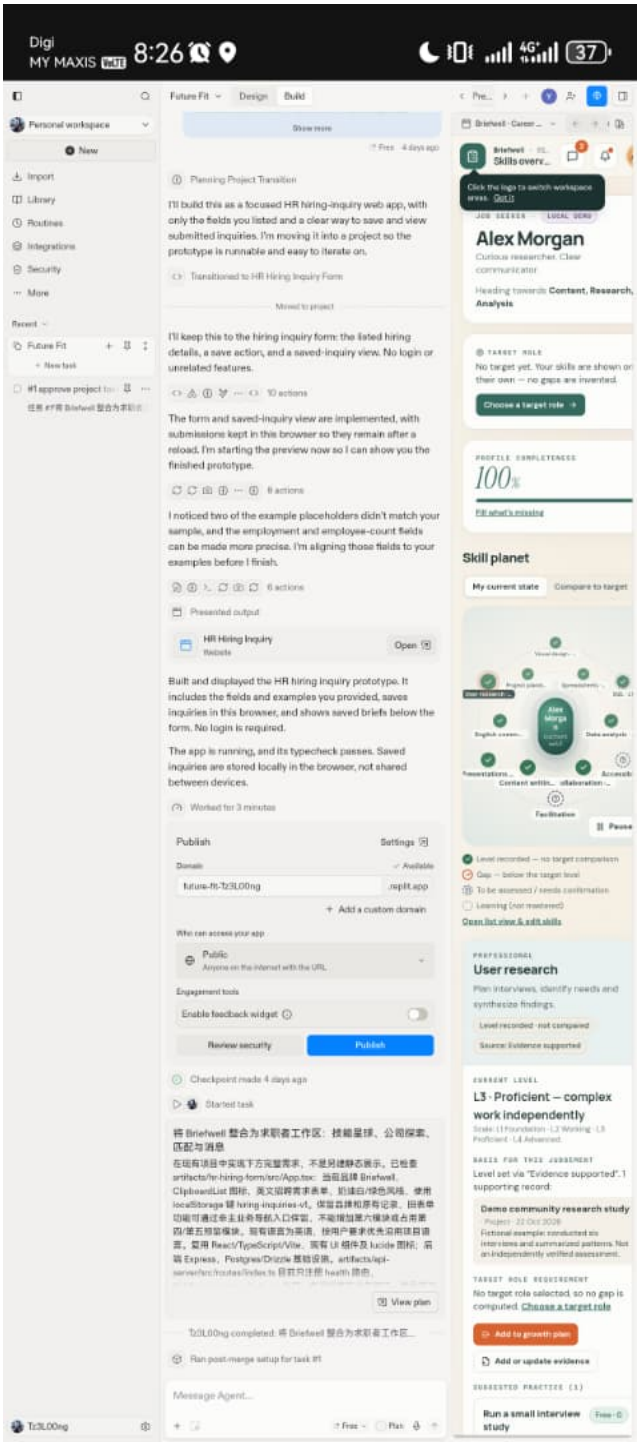

Figure 4. Replit Agent task history and Future Fit prototype preview.

The preview pane contains an intermediate internal prototype label visible during development. The Replit workspace title identifies the project as Future Fit. The final product identity is Future Fit (Aligna).

4. Replit AI Usage Evidence

The Replit account usage page records AI usage during the displayed billing period. The screenshot shows total usage of US$13.92 and identifies AI usage of US$13.92 in the resource breakdown. It also shows the remaining account allowance and one active user.

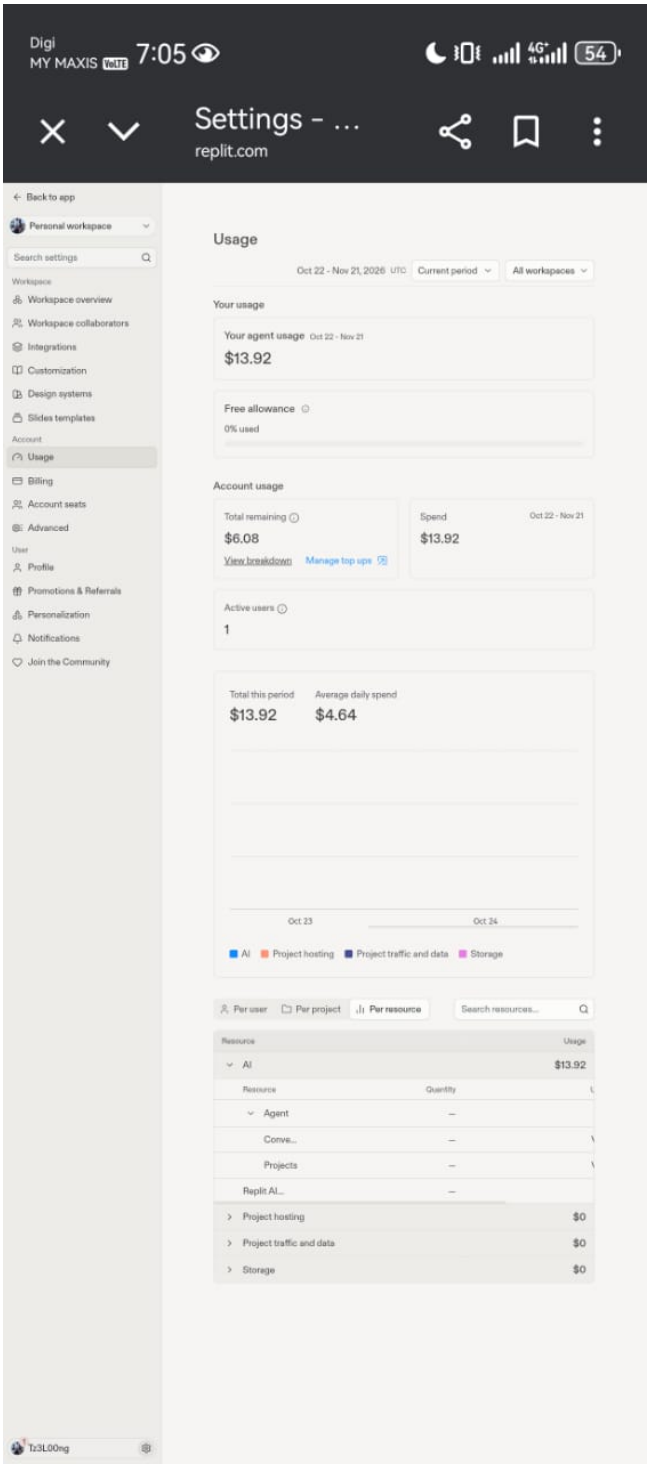

Figure 5. Replit account usage page showing recorded AI usage.

This is account-level usage evidence for the displayed period. It supports the team's use of Replit Agent during prototyping; it is not presented as a line-item cost audit of the final Vercel deployment.

5. Relationship to the Final Implementation

Replit contributed to the early prototype and AI-assisted development process. The team subsequently refined the product in its local Node.js repository. The final public prototype uses Vercel for deployment and Firebase for authentication and data services. Replit is part of the documented development history, but it is not the runtime dependency of the final production version.

Replit stage	Initial prototype and interface exploration using Replit Agent.
Local stage	Feature integration, testing and final refinement in the team's Node.js repository.
Deployment stage	Final public prototype deployed through Vercel at https://aligna-two.vercel.app/.

The evidence in this document does not claim that the final production system was fully developed or deployed on Replit. It demonstrates the sponsor-provided resource, Agent activity, prototype preview, checkpoint history and recorded AI usage.

6. Evidence and Privacy Notes

- The SDC Replit redemption code is not reproduced in this document.

- No passwords, API keys, private tokens or personal records are included.

- The account usage screenshot shows account-level information and should be submitted only as permitted by the team and organiser.

- The team should keep the product name consistent in the final evidence package and explain any intermediate prototype label if necessary.

Conclusion

The evidence confirms that the team used the official SDC-sponsored Replit Core resource and Replit Agent during the early development of Future Fit (Aligna). Replit supported requirements exploration, prototype generation and interface iteration. The final product was later refined locally and deployed through Vercel.
